Goat buck sperm doses are kept at 4 °C in refrigerated form. As a cold-shock sensitive species, chilling to 4 °C must be slow, which delays the doses delivery and their insemination. However, the time of transportation could be used for chilling. We studied if the sperm quality was similar between a system developed for chilling the doses during transportation and the programmable water bath (WB) in the lab. Twelve Murciano-Granadina bucks were used. The concentration in each ejaculate (n = 12) was adjusted to 560×10^6 sperm/mL with skimmed milk-glucose (0.2%; w:v) and semen was loaded into 0.25 mL plastic straws that were split into two treatments: half were chilled in a WB (in 90 min; theoretical cooling rate: -0.18 °C/min) and the other half in a cooler (C; during 3h 45min; average cooling rate: -0.09 °C/min). Total motile (%TM) and progressively motile (%PM) sperm were evaluated with a CASA system and live sperm (%LS) were evaluated with SYBR14/propidium iodide in a flow cytometer, according to the protocols from Konyali et al. (2013. Cryobiology, 67: 124-131). Fresh semen presented an average quality of $74.1\% \pm 2.2$ TM, $49.4\% \pm 2.8$ PM and $64.1\% \pm 2.9$ LS. Straws chilled in WB and C exhibited similar TM ($72.0\% \pm 4.3$ and $76.3\% \pm 4.3$) and PM sperm ($50.5\% \pm 5.7$ and $49.5\% \pm 5.7$). However, straws chilled in C presented higher ($P < 0.05$) LS ($67.8\% \pm 5.2$) than samples chilled in WB ($55.4\% \pm 5.2$). In conclusion, straws chilled in the system adapted to the cooler exhibited similar percentages of motile but higher percentages of live sperm than samples chilled in the programmable water bath.
